Global tag: 111X_mcRun4_realistic_T15_v1

Era: eras.Phase2C9

Geometrie: Configuration.Geometry.GeometryExtended2026D49_cff

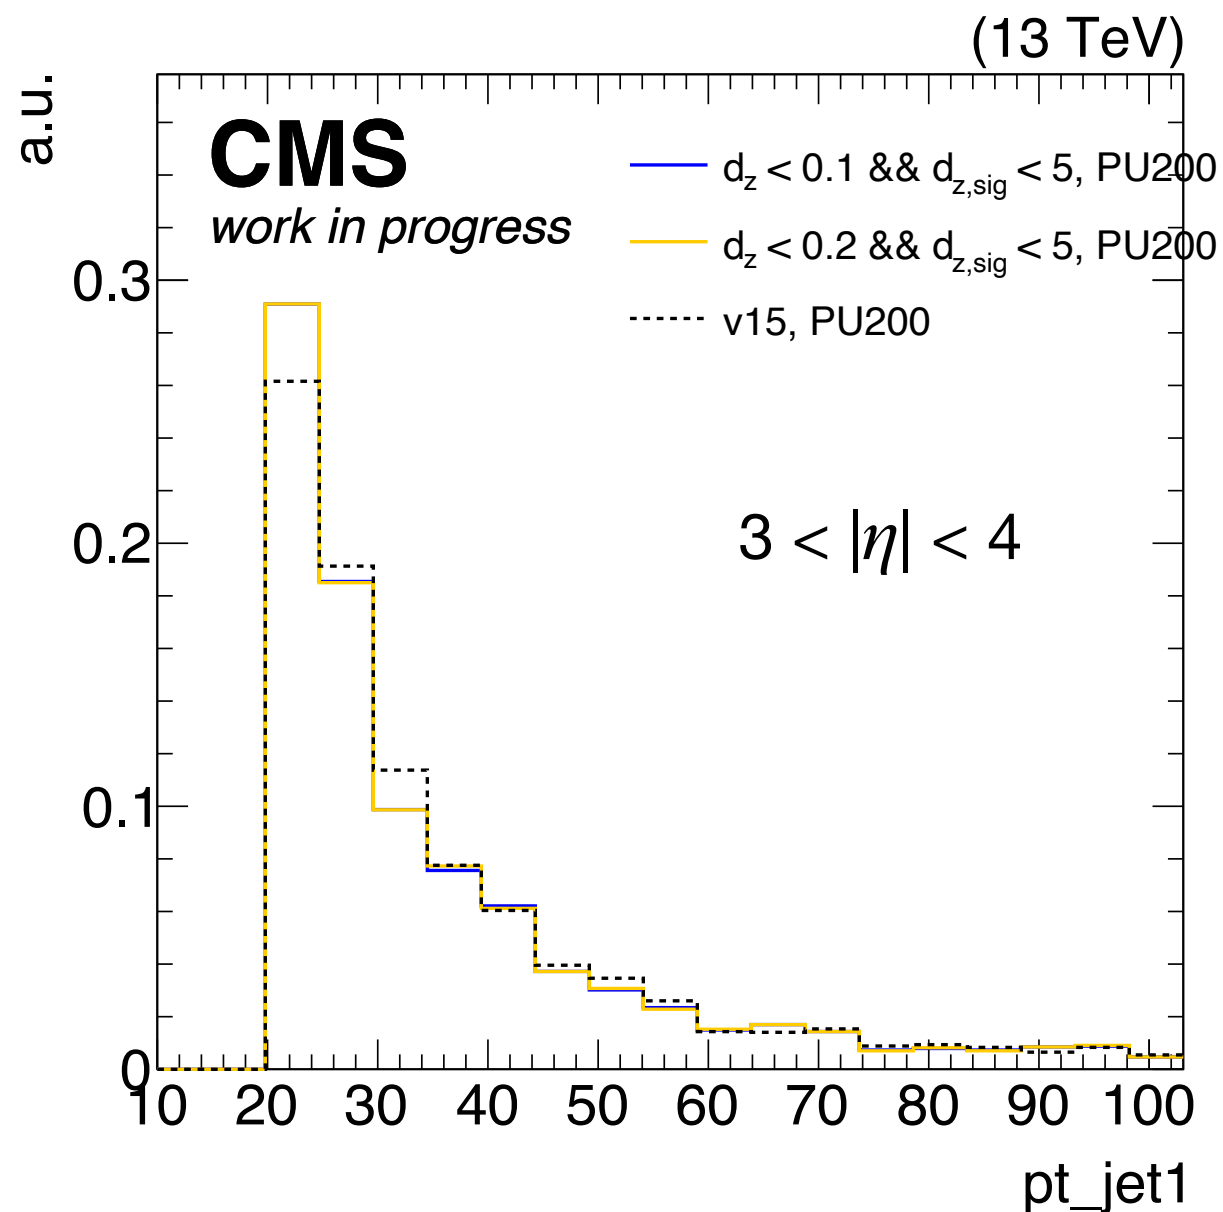

Code and Framework:

https://github.com/abenecke/UHH2/tree/CMSSW11X_vertexing_dz0p1_dzsig5

https://github.com/abenecke/cmssw/tree/CMSSW11X_vertexing_PR

Note: For all samples events are rejected if LV is not the first element in the collection. This is done by calculating the minimal distance between MC truth z position and vertex z position.

Different scenarios

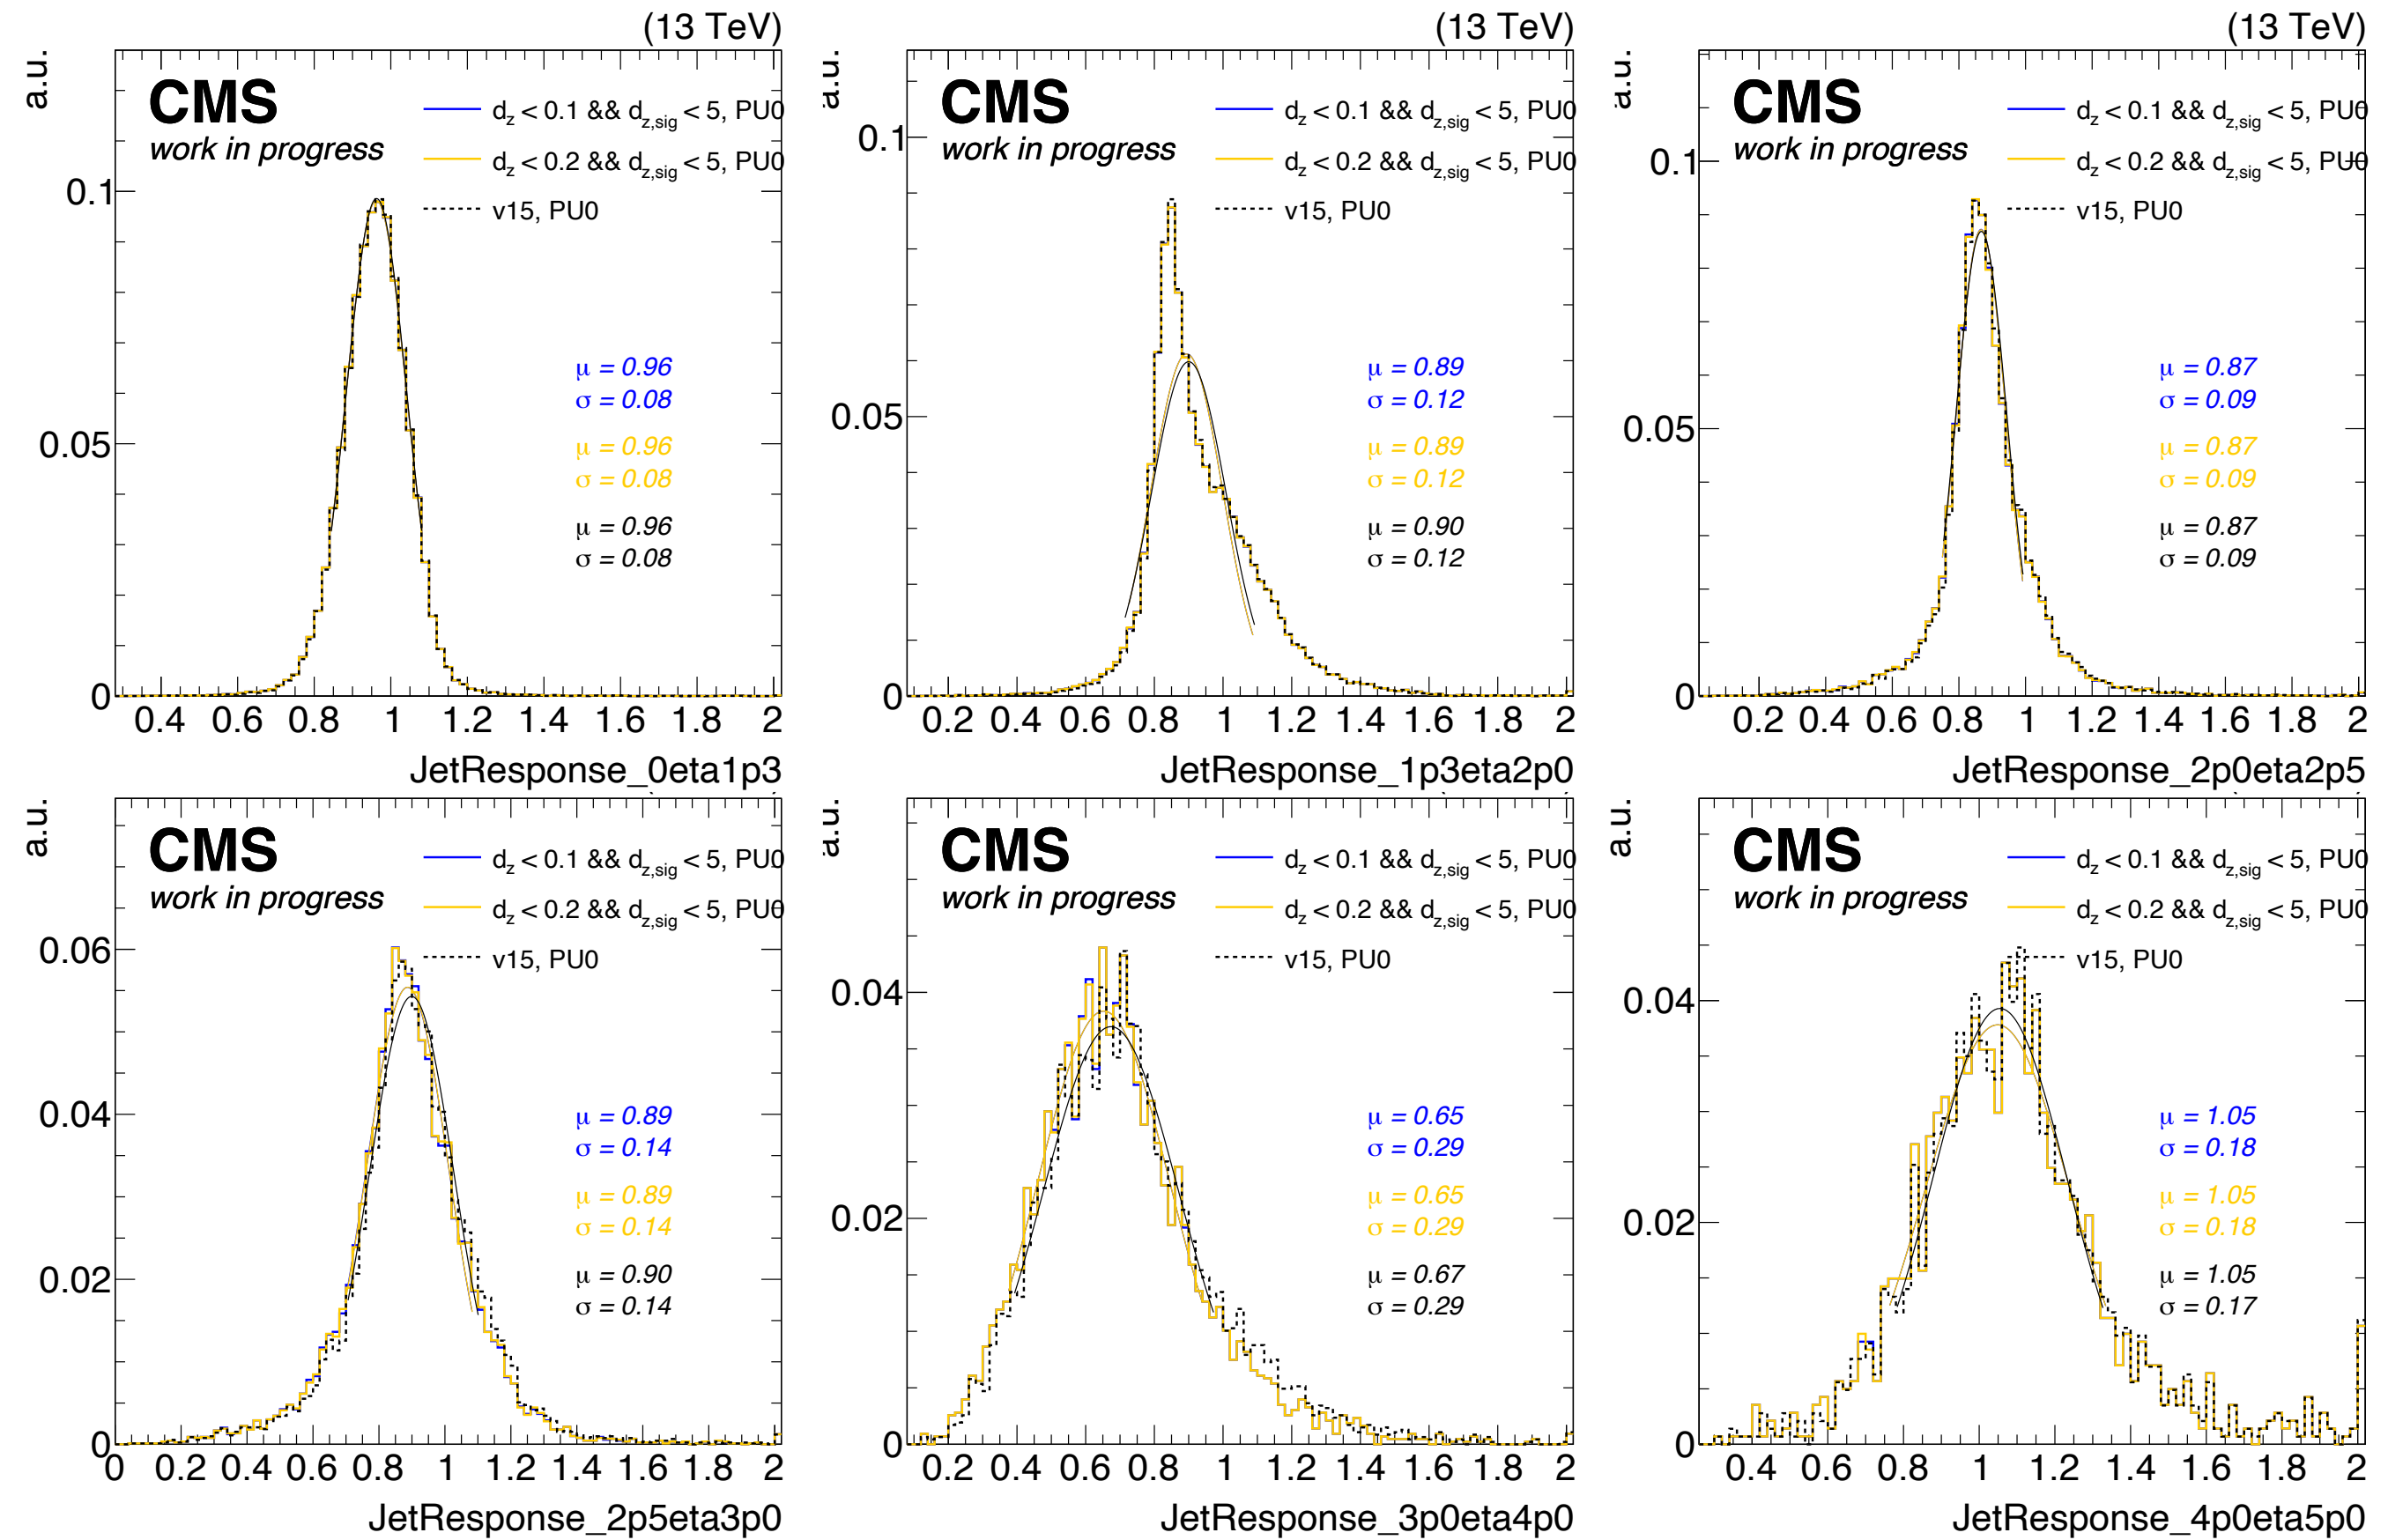

- Three different scenarios tested:
 - UL v15 PUPPI
 - PR vertex assignment with $d_z < 0.1 \ \&\& \ d_{z,\text{sig}} < 5$
 - PR vertex assignment with $d_z < 0.2 \ \&\& \ d_{z,\text{sig}} < 5$
- First look into 4D vertex collection w/o timing
- In PR we find the closest vertex for each track that fulfills d_z and $d_{z,\text{sig}}$

Comparison of jet response

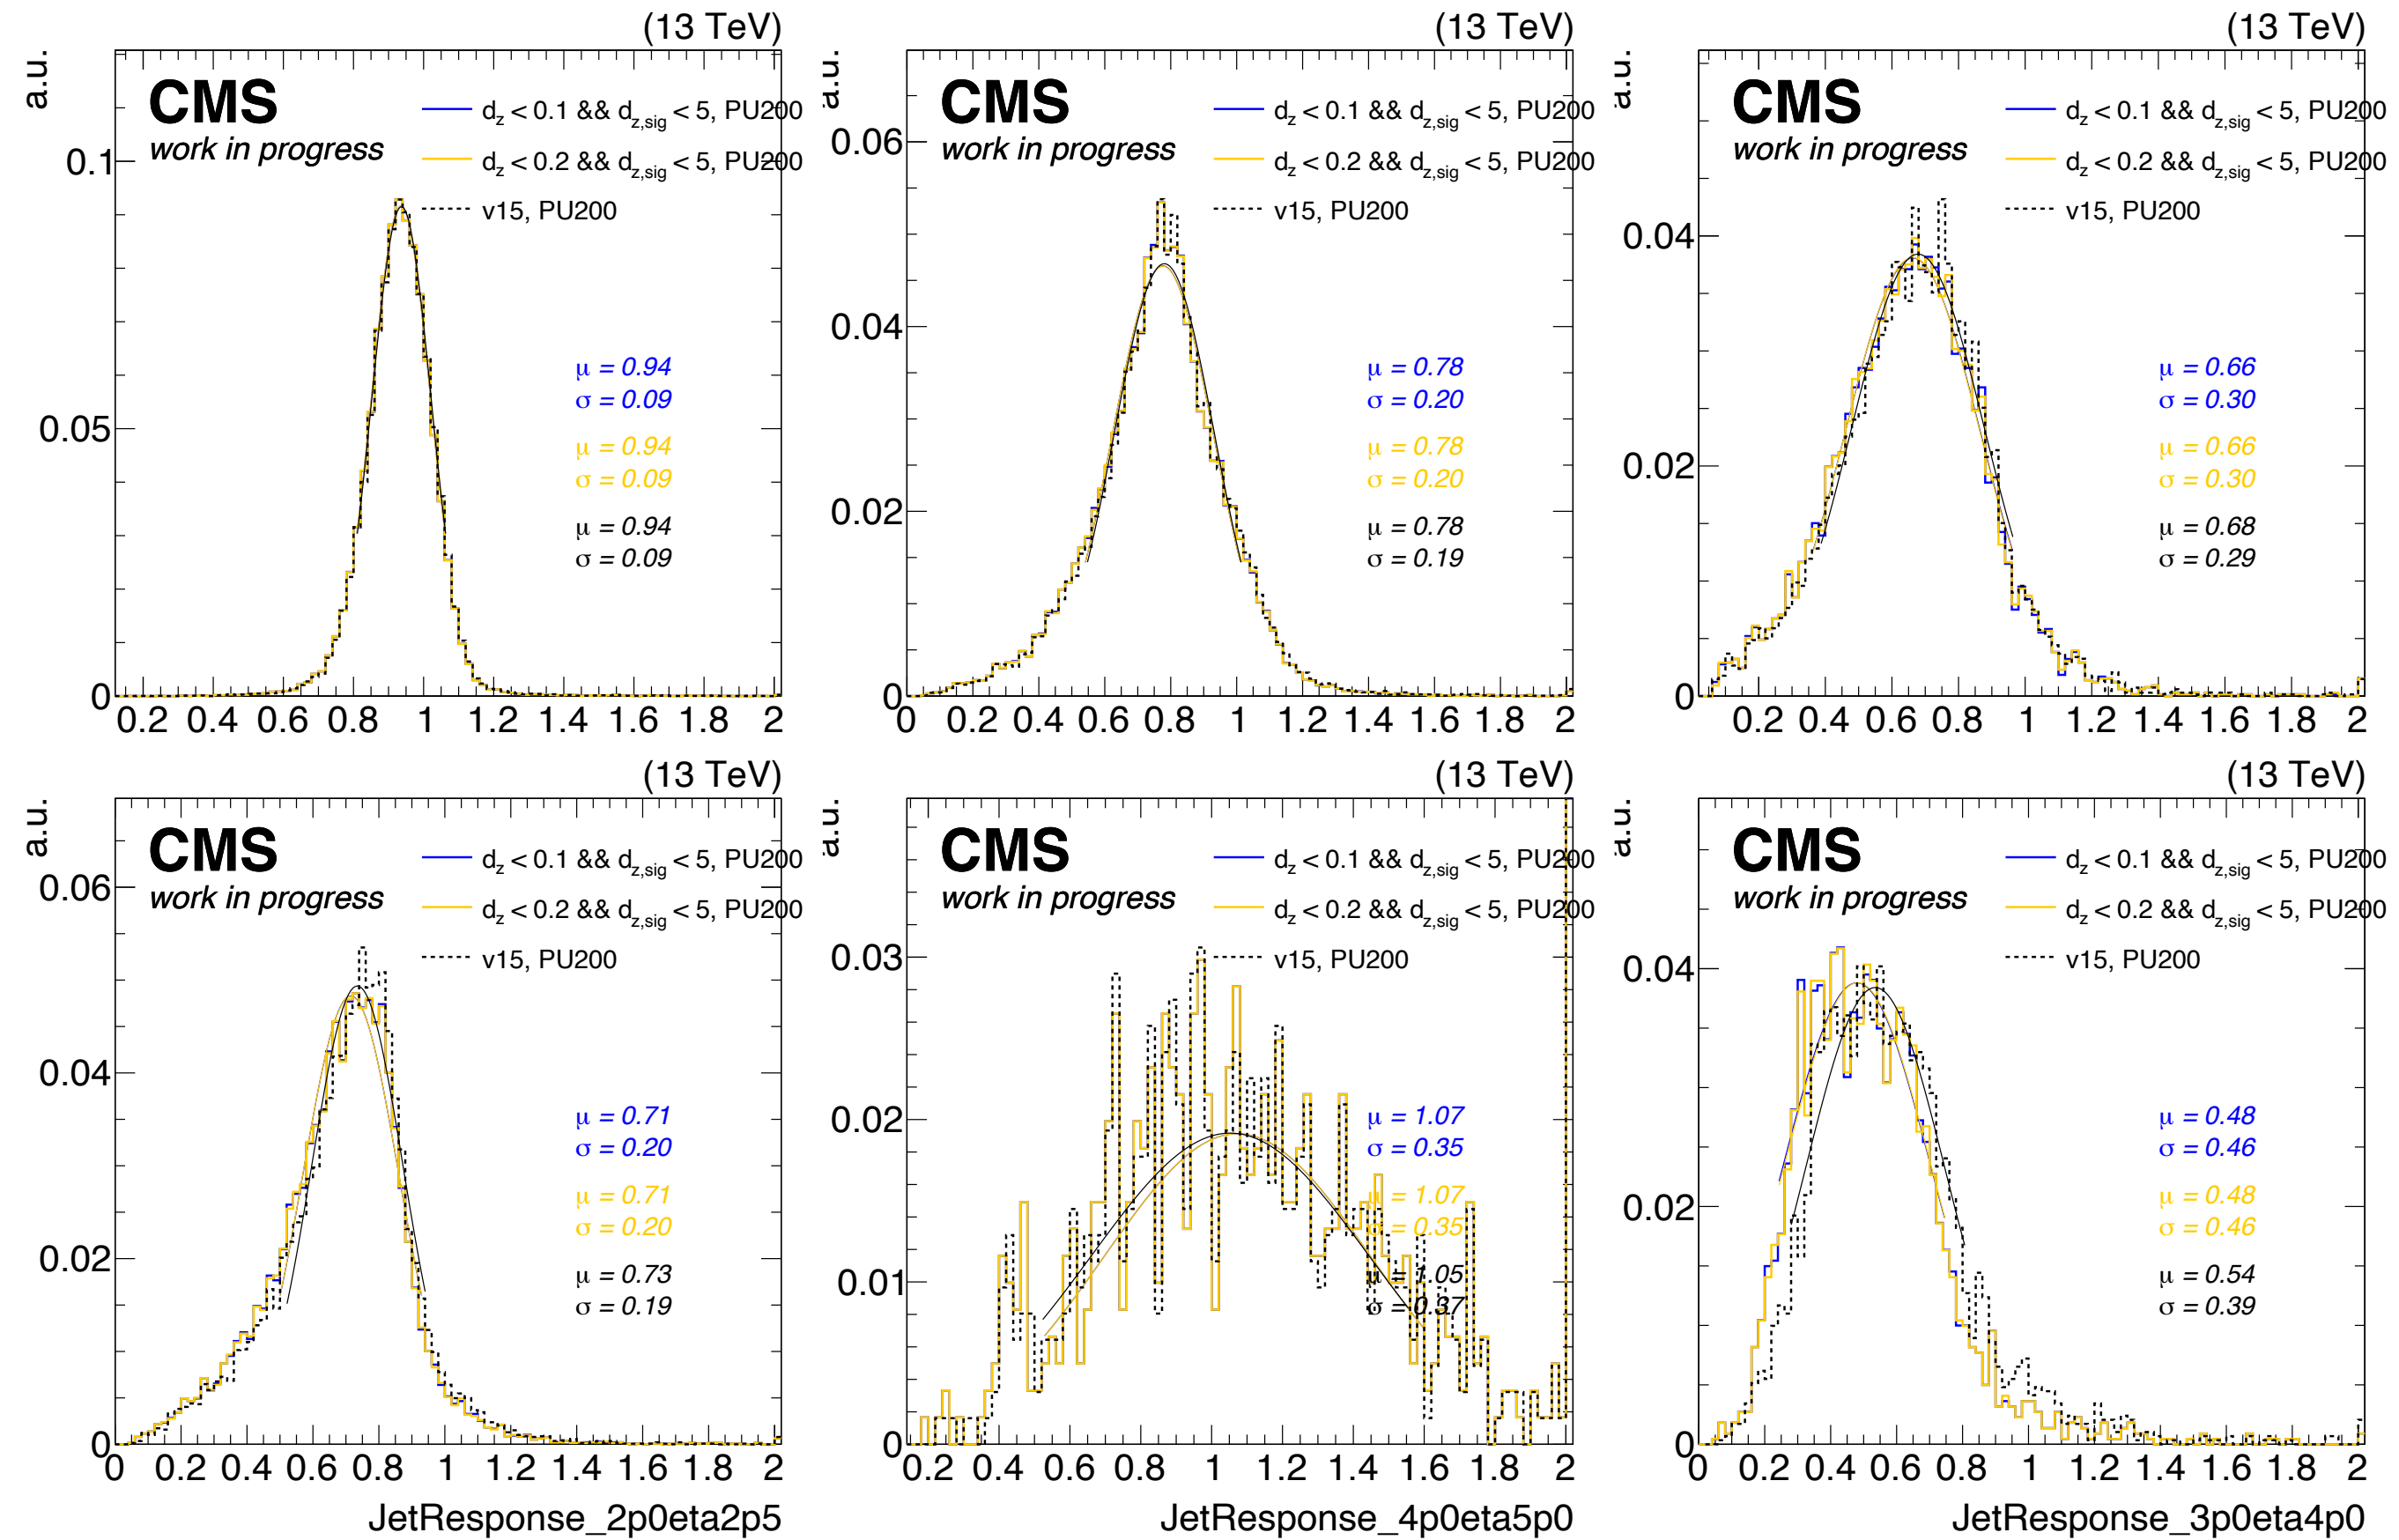

Only small difference observed in the different η bins.

For PU of 200 in the high η region a bit more difference; v15 better than dz.

Jet response 0PU

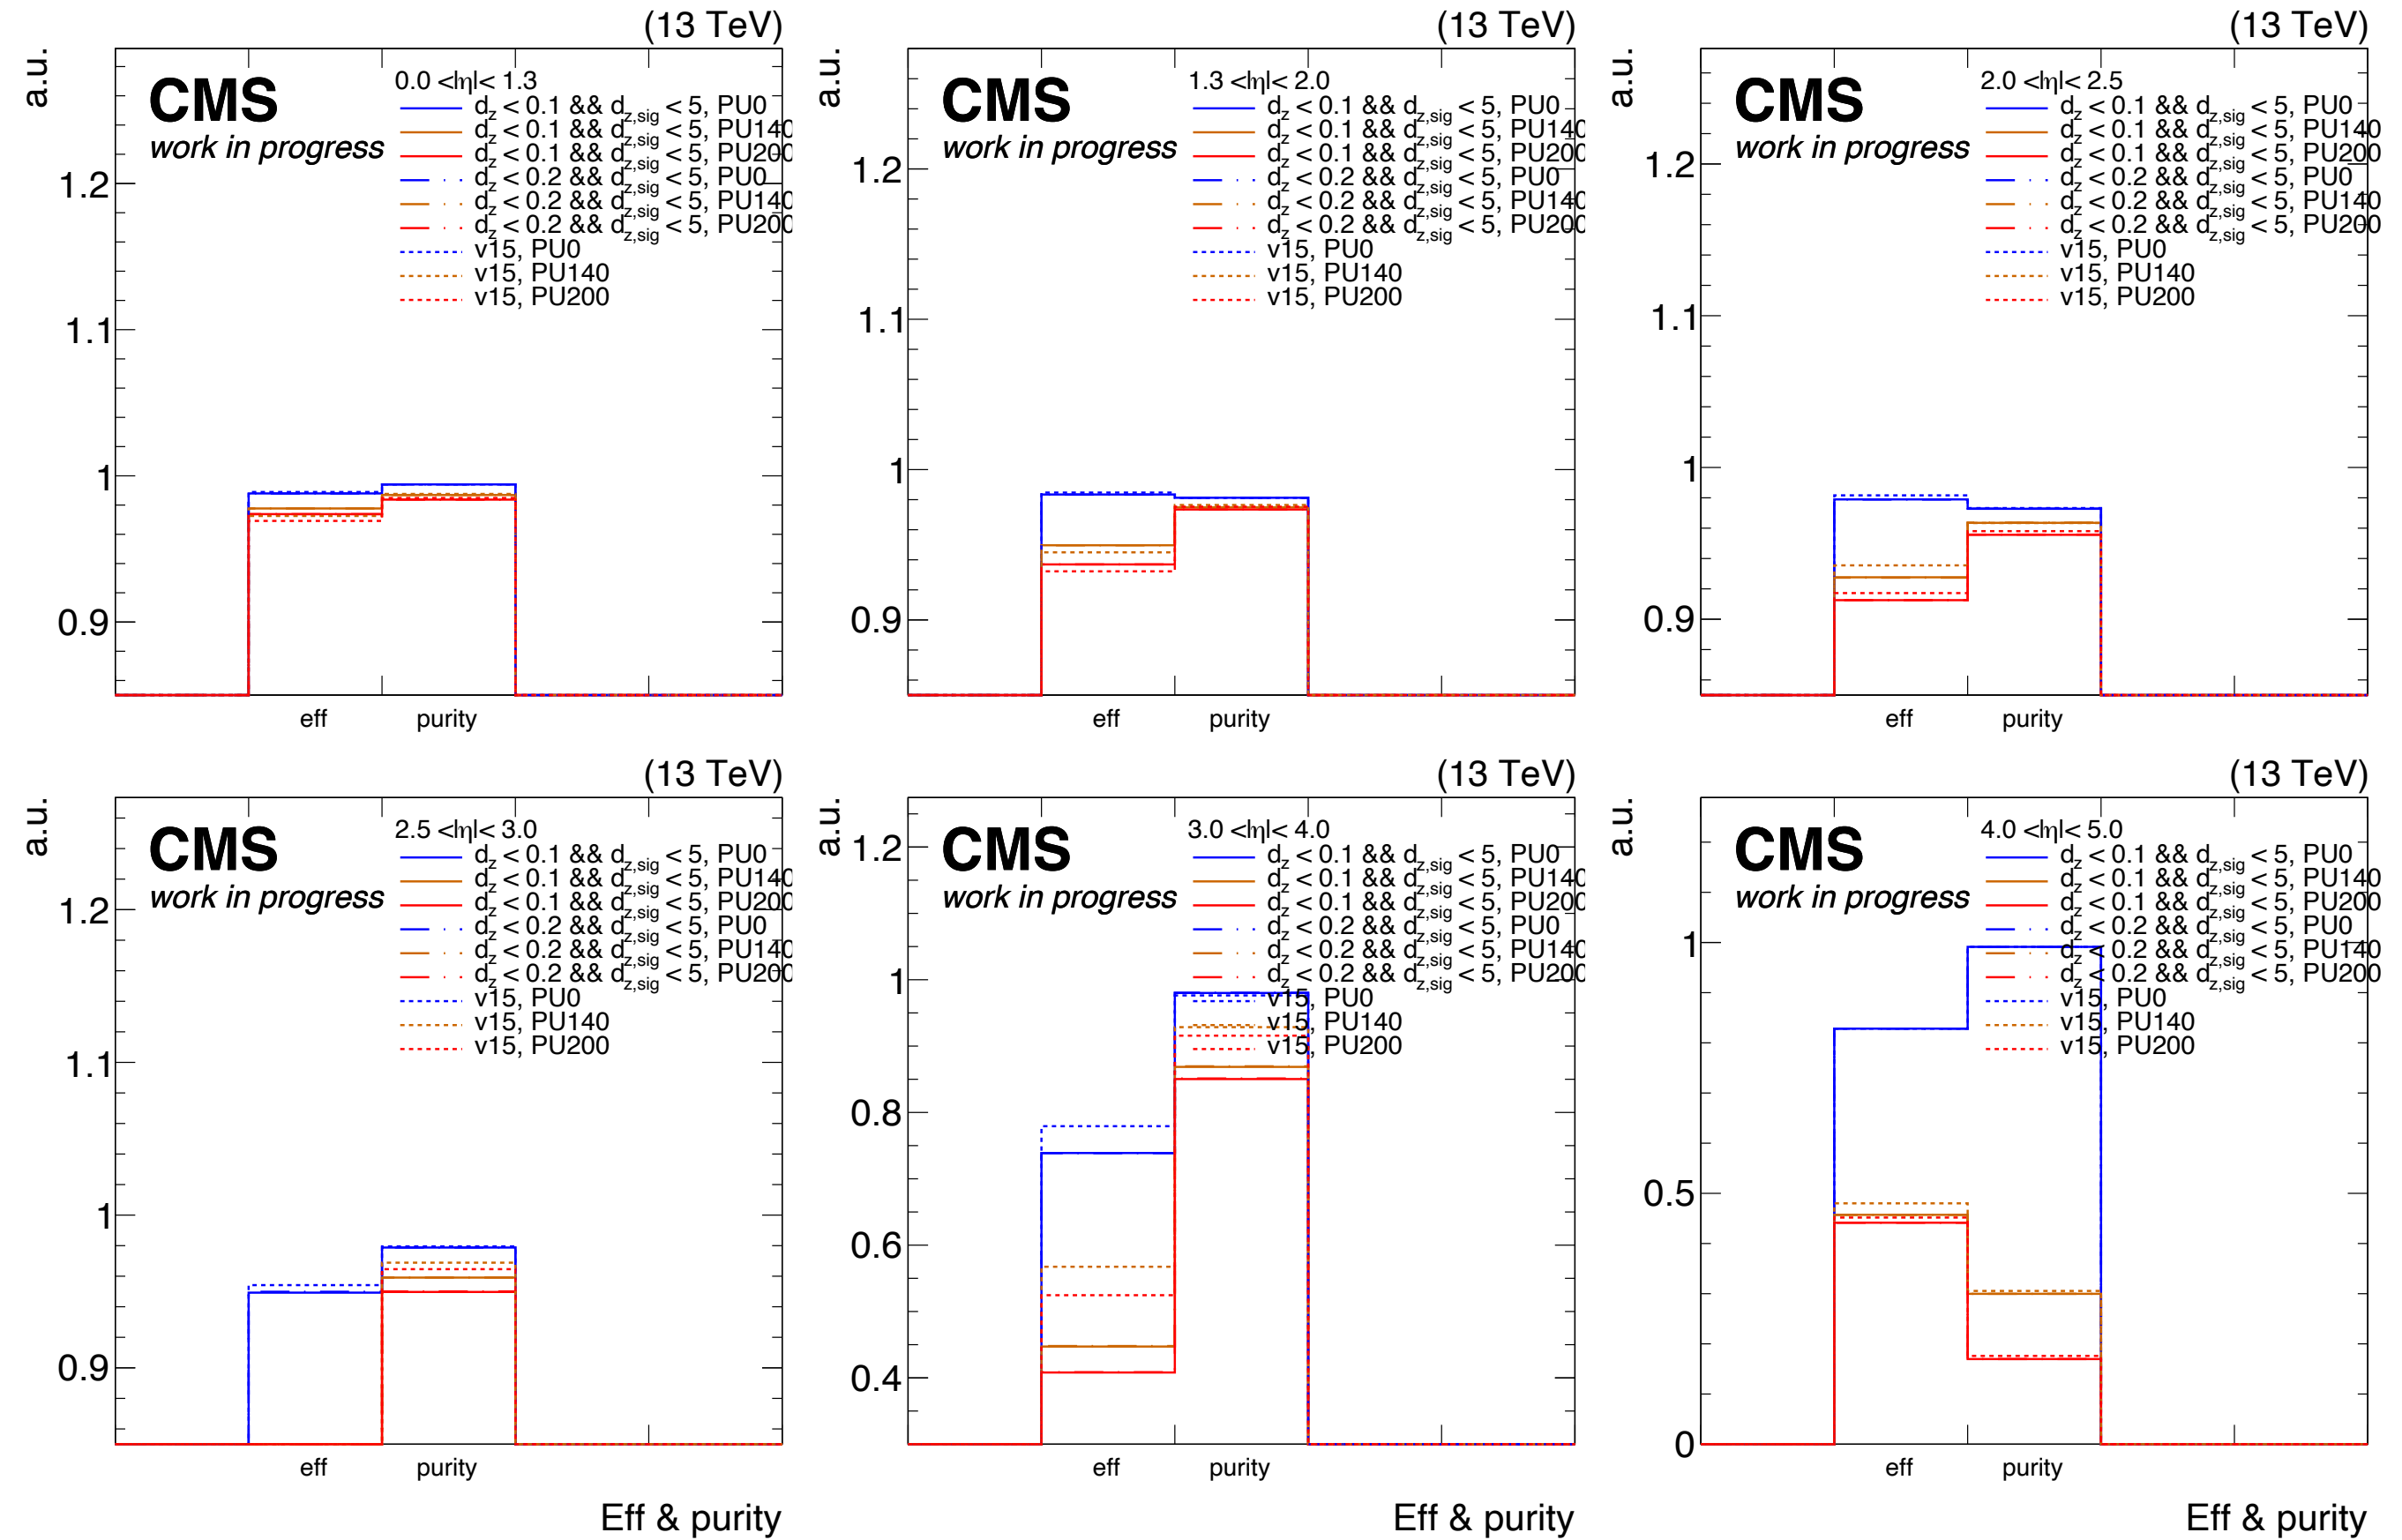

Jet response 200PU

Efficiency and purity

Small differences in $|\eta| < 2.0$. Better eff and purity in $|\eta| > 2.0$ for v15 than dz.

Efficiency and purity

Track-Vertex Variables

3D vertex collection

In the following dz , $dzsig$ and $dzsig(dz<0.1)$ are shown first inclusive than in different η bins. Track vertex association to closet vertex in z that fullfills $dz<0.1$ && $dzsig<5$. Three PU scenarios are compared while the 0 PU scenario can give us a hint on the resolution of the variables. Variables are shown without PUPPI weights. Small differences between the η bins.

General

$$|\eta| < 1.3$$

$$1.3 < |\eta| < 2.0$$

$$2.0 < |\eta| < 2.5$$

$$2.5 < |\eta| < 3.0$$

The dzsig cut might be too tight, since no significant difference between 0PU (blue) and 200PU (red) is visible. This could result in reduced eff.

$$3.0 < |\eta| < 4.0$$

The $dz+dzsig$ cut might be too tight, since the 0PU (blue) scenario shows a broader spectrum. This could result in reduced eff.

$$4.0 < |\eta| < 5.0$$

The $dz+dzsig$ cut might be too tight, since the 0PU (blue) scenario shows a broader spectrum. This could result in reduced eff.

4D vertex collection

Similar picture as for 3D vertex collection. In the high η region the dzsig cut might not be useful. Also the dt requirement could still be optimised.

General

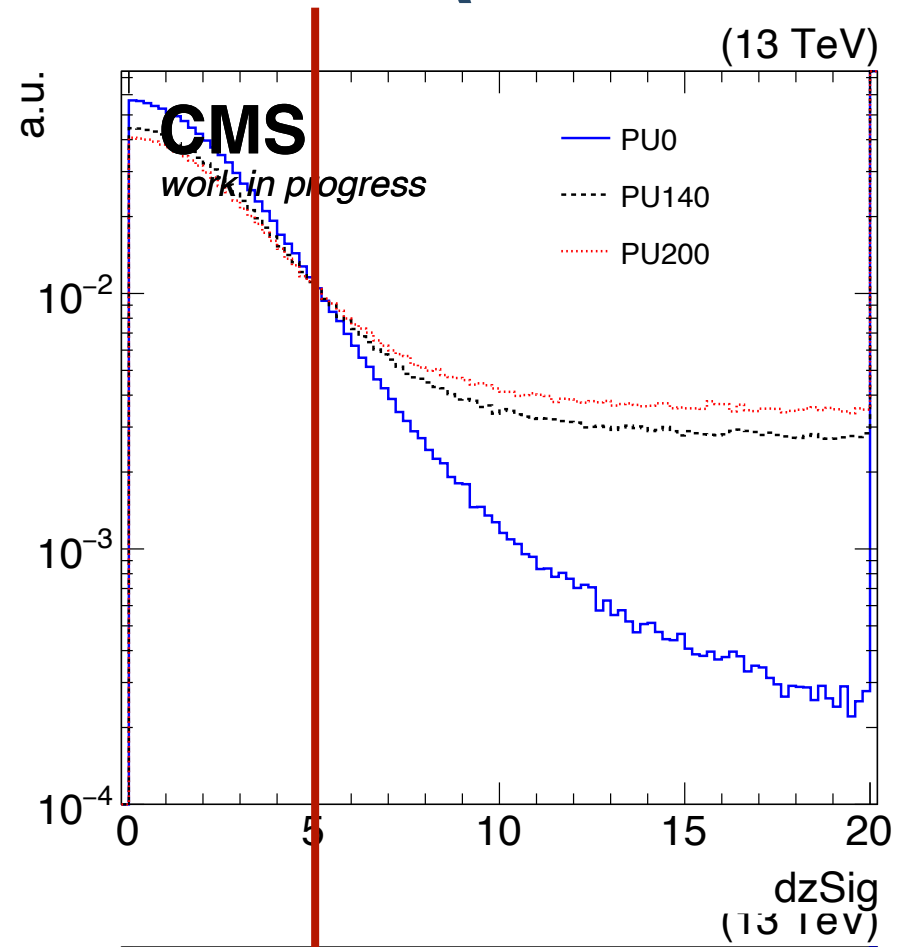

$$|\eta| < 1.3$$

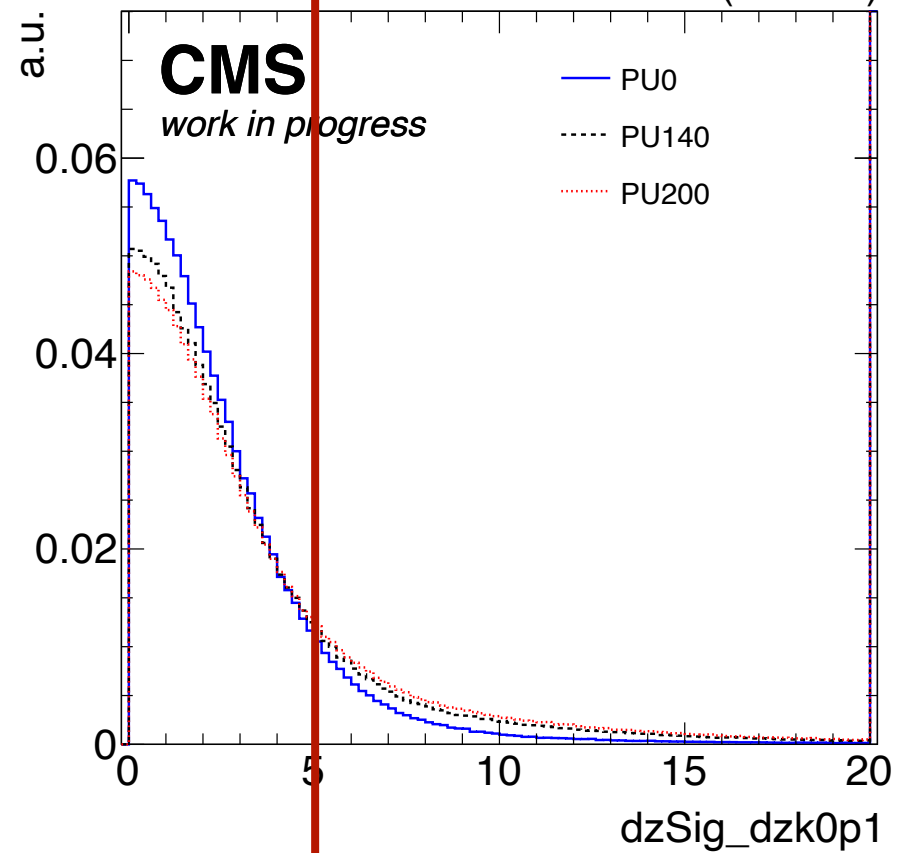

$$d_z < 0.1$$

$$1.3 < |\eta| < 2.0$$

$$d_z < 0.1$$

$$2.0 < |\eta| < 2.5$$

$$d_z < 0.1$$

$$2.5 < |\eta| < 3.0$$

$$d_z < 0.1$$

$$3.0 < |\eta| < 4.0$$

$$d_z < 0.1$$

$$4.0 < |\eta| < 5.0$$

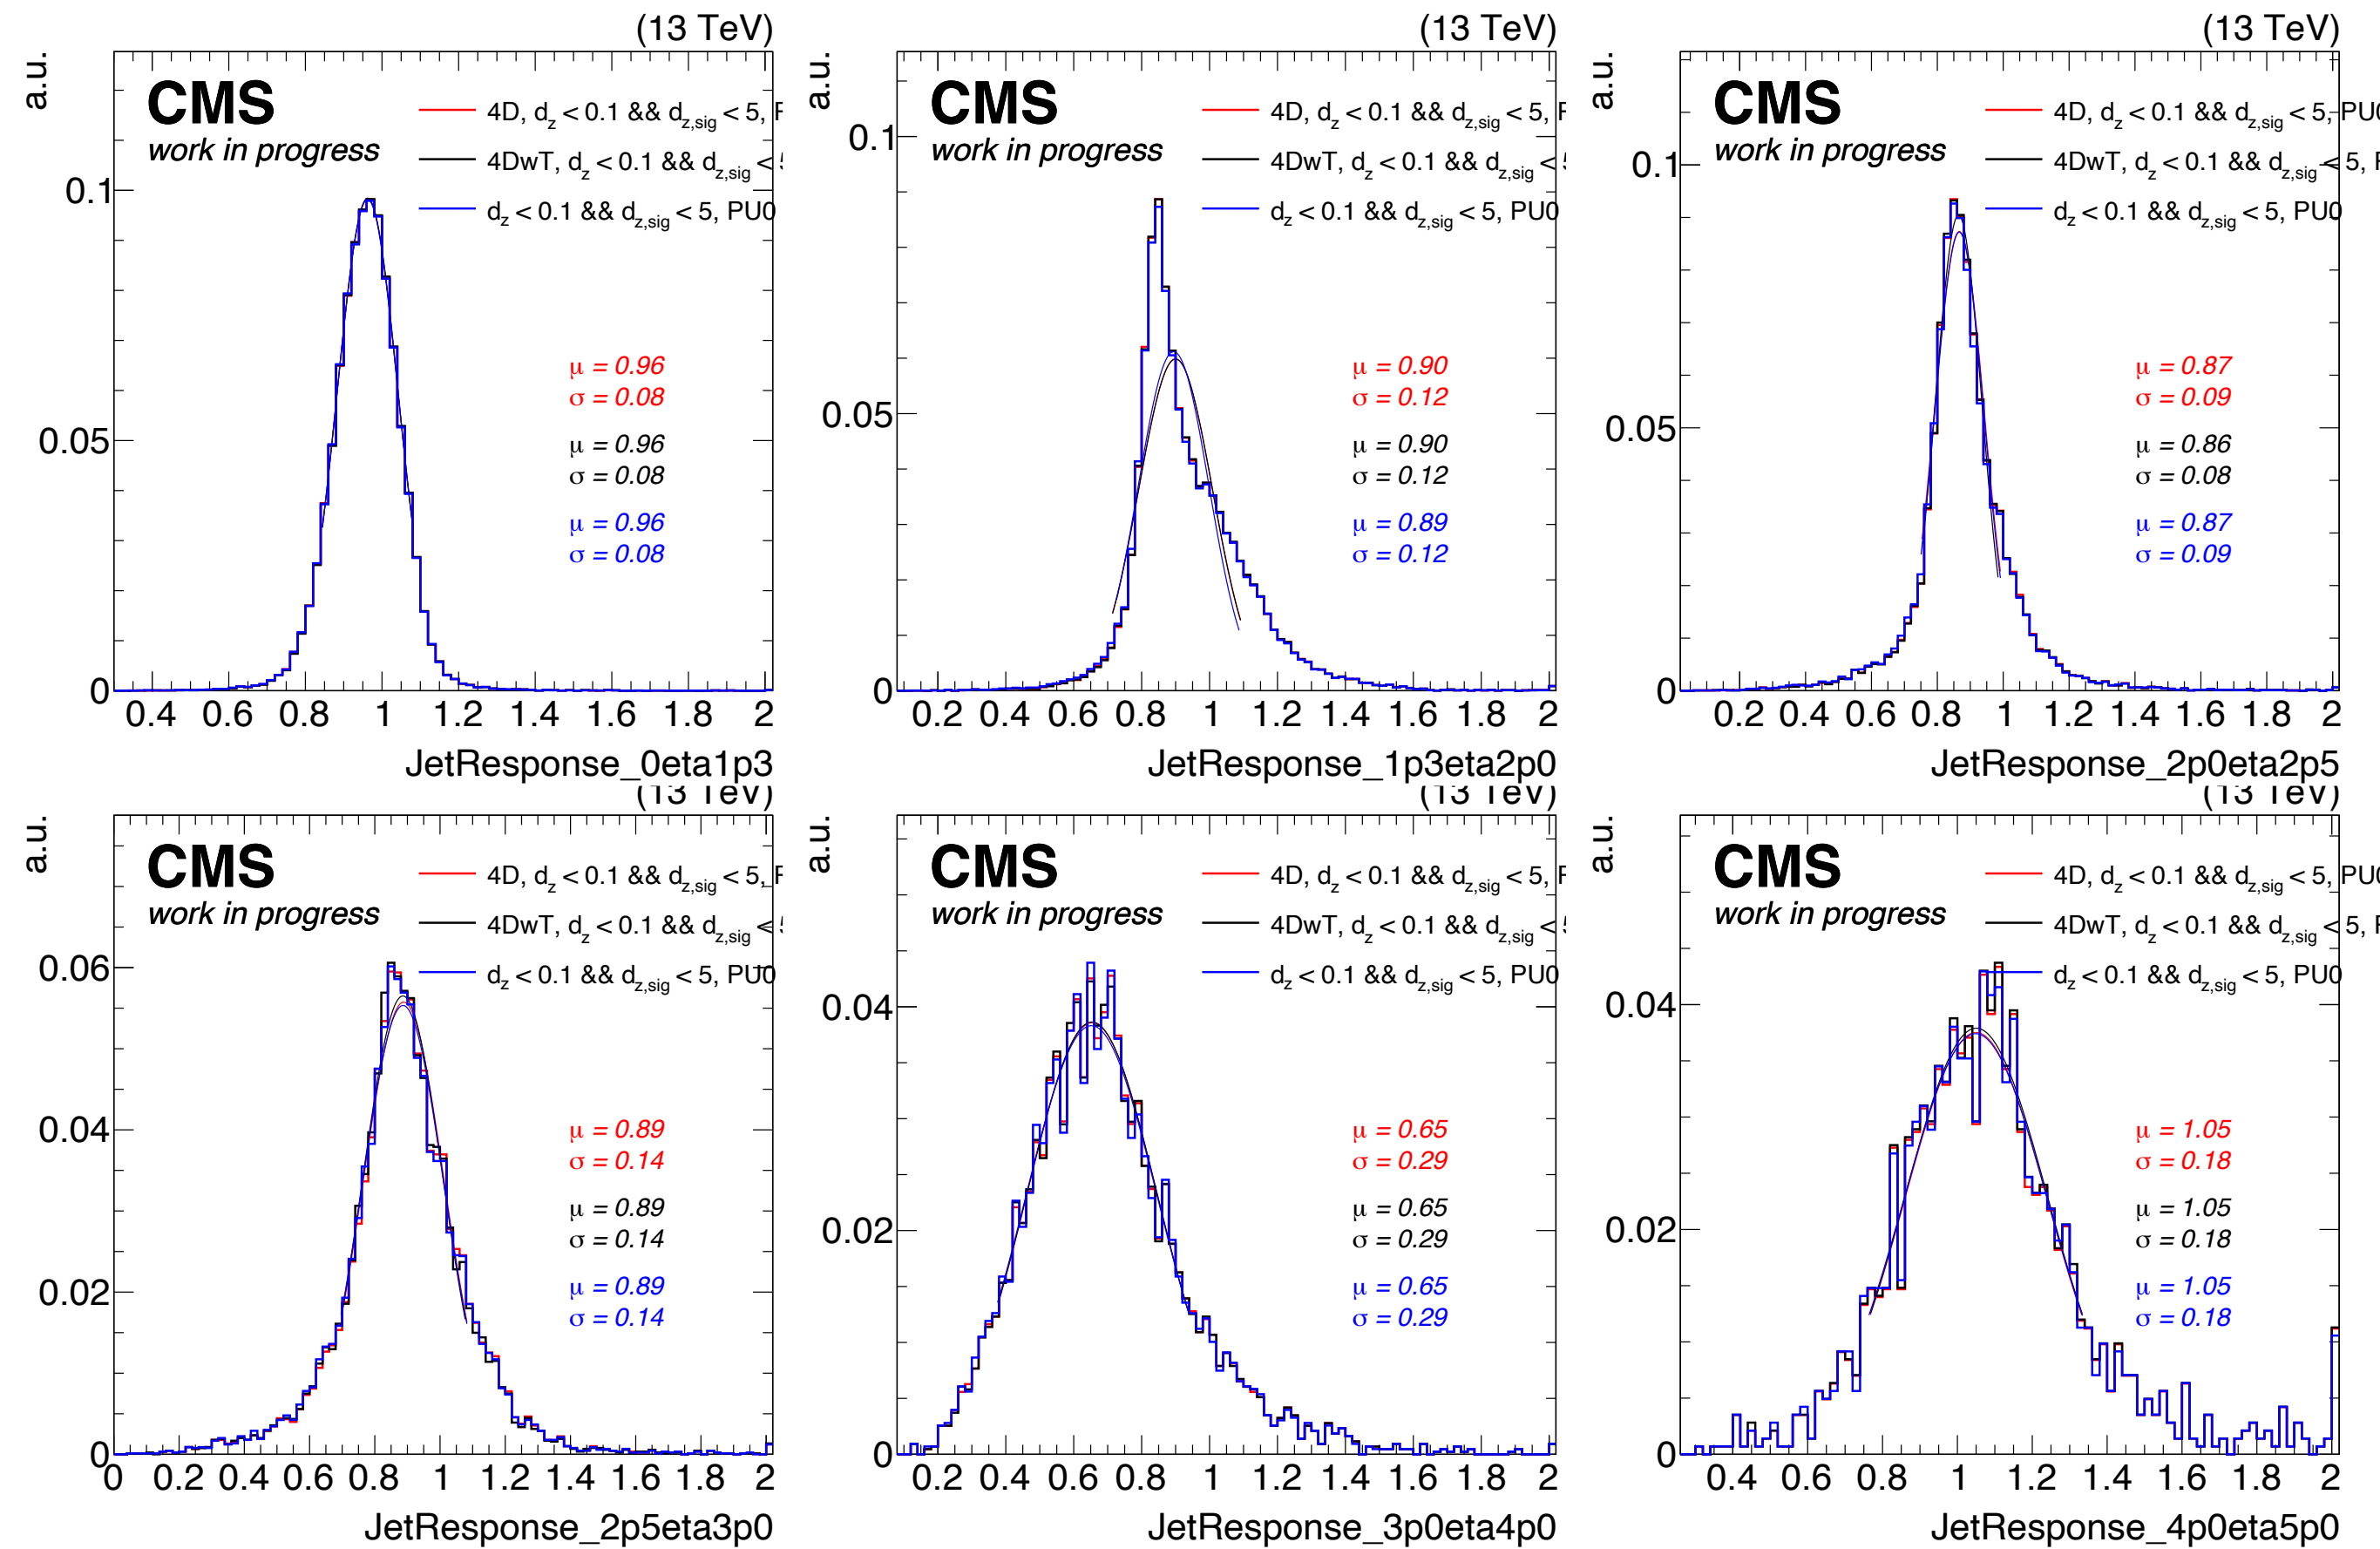

$$d_z < 0.1$$

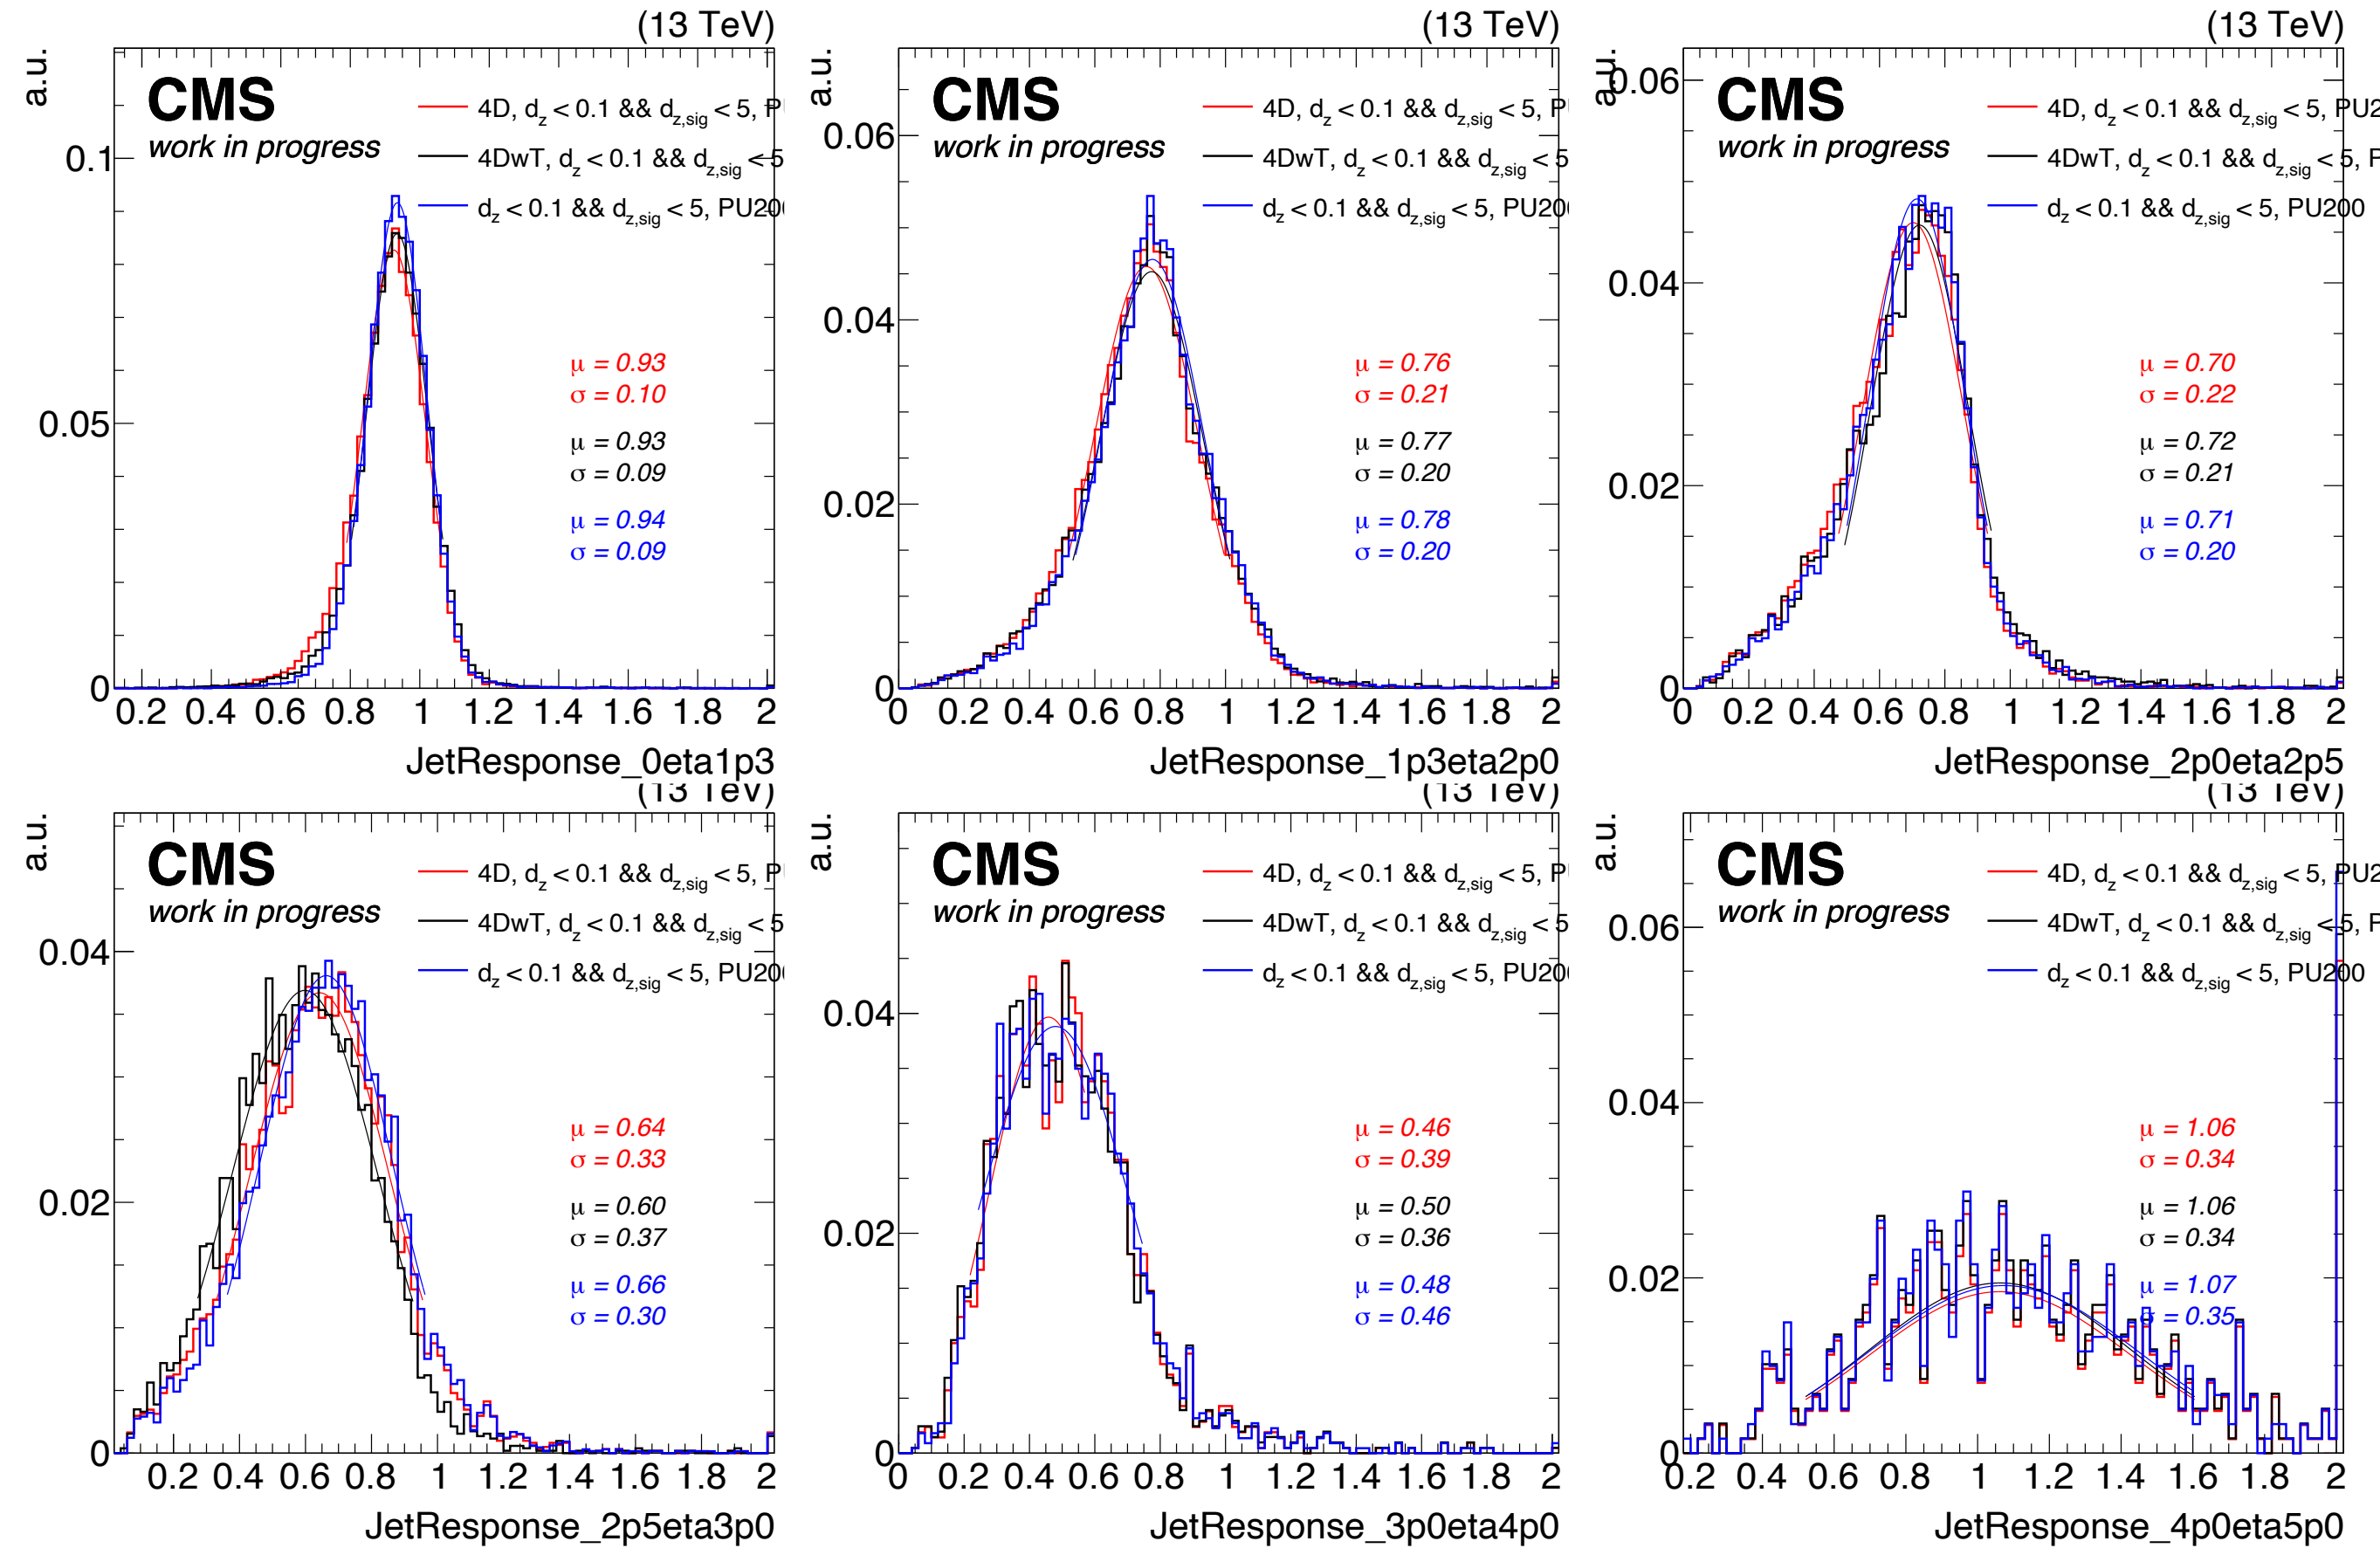

Comparison of response

No big differences between the 3D dz version and the 4D dz version. Although in the high η region a difference in the width and mean of the fit is visible.

Jet response 0PU

Jet response 200PU

Efficiency and purity

4D vertex collection has a lower efficiency compared to 3D, especially when applying a timing requirement.

Eff & purity

Summary

- Showed different track-vertex association scenarios with the new PR
- Phase-2 sample with three different PU (0, 140, 200) scenarios were studied.
- With 3D vertex collection: v15 tune seems to perform slightly better than dz
- With 4D vertex collection: efficiency reduced compared to 3D dz version, especially with time requirement
- Test dz scenarios also on Run3 samples?
- Optimize dz+dzsig and allow η dependent requirements?
